Managing maxillary proclination with novel designed angulated implants

INTRODUCTION

Nonsplinted attachments (such as ERA or locators) are preferred as attachments for removable dental prostheses as they are more economical, less technique sensitive, easier to clean, repair, and maintain than splinted (bar and clip) attachment systems, but they work favorably only when implants in the arch are placed parallel to each other. However, implants in the anterior maxilla may have to be placed with a labial inclination (tilted) owing to the proclination of the premaxilla, making it challenging to achieve parallelism between anterior and posterior implants, and thereby necessitating the use of angled abutments. Recently, a novel implant design with a 12° restorative platform angulation has been introduced by Southern Implants (Co-axis, Keystone Dental, Inc., Burlington, MA, USA). These new angulated implants aid in minimizing the divergence between the anterior and posterior maxillary implants without using angled abutments. The purpose of this article was to report a case utilizing the novel angulated implants (Co-axis, Keystone Dental, Inc., Burlington, MA, USA) in the premaxilla for fabrication of maxillary removable dental prostheses supported and retained by nonsplinted attachments.

Key Words: Angle correction, angled abutment, Co-axis, divergent, implants, novel design
A novel implant design, with 12° and 24° (available in US and Europe) prosthetic axis correction, has been introduced recently by Southern Implants (Co-axis, Keystone Dental, Inc., Burlington, MA, USA). These implants permit correction of the restorative trajectory of the tilted implant without the use of angled abutments.\cite{5-7} The purpose of this article was to report a case utilizing the novel implants in the premaxilla for fabricating a nonsplinted attachment-supported maxillary removable dental prostheses.

**CASE REPORT**

A 45-year-old Hispanic male presented to our clinic with a chief complaint of difficulty in chewing food and discomfort associated with increased palatal coverage of existing maxillary restoration. The patient had a noncontributory medical history and was edentulous in the maxillary arch and partially edentulous in the mandibular arch, missing tooth #17, #18, #19, and #32 (lost 2 years ago due to caries and periodontal disease) [Figure 1]. The patient had received a complete denture in the maxillary arch and a serviceable cast partial denture in the mandibular arch. The oral hygiene of the patient was fair, and he desired a new and an “easy to maintain” maxillary restoration. The following treatment plan was presented to the patient after a thorough consideration of his clinical condition and oral hygiene compliance, and his preferences were:

- Planning and placement of 5–6 implants in the maxilla with optimal anteroposterior spread
- Fabrication of an open palate maxillary removable dental prostheses supported by nonsplinted attachments.

The treatment was initiated on receipt of the patient consent. The procedural steps are described below:

**Acquiring cone-beam computed tomography scan and planning implant placement**

The cone-beam computed tomography (CBCT) scan revealed the proclination of the premaxilla which would require the anterior implants to be placed with a labial inclination, resulting in divergence between anterior and posterior implants of approximately 12° [Figure 2a and b]. This would necessitate the use of bar and clip attachment system or angled abutments, resulting in insufficient restorative space available for the definitive prosthesis (as depicted by the CBCT). Hence, novel-designed angulated implants (Co-axis, Keystone Dental, Inc., Burlington, MA, USA) were planned for the anterior maxilla [Figure 3]. A total of five implants were planned, of which three implants in the anterior maxilla (#6-Keystone 12° Co-Axis, 4.0 × 13 ex-hex, #8-Keystone 12° Co-Axis, 4.0 × 13 ex-hex, and #11-Keystone 12° Co-Axis, 4.0 × 13 ex-hex) and two in the posterior maxilla (#3 and #14 Nobel Active 4.3 × 11.5, Nobel Biocare, Yorba Linda, CA, USA).

**Implant surgery**

It is critical to time the rotation of the novel angulated implants accurately so that the angle correction occurs at the desired depth. A dimple on the facial aspect of the implant mount is provided by the manufacturers to guide the orientation of the implant.

Under moderate, intravenous sedation and local anesthesia, the implants were placed in the planned locations using a
three-dimensional surgical guide (NobelProcera, Mahwah, NJ, USA) [Figures 4-6]. The existing maxillary denture was adjusted, relieved and relined with a soft reline material (MucoSoft, Parkell, Inc., Edgewood, NY, USA).

Definitive prostheses placement
The implants were allowed to heal for 4 months. Restoration of the novel designed implants follows standard prosthetic fabrication procedures as the prosthetic platform is treated as a standard implant. Definitive maxillary removable dental prosthesis with a metal framework[8] [Figure 7] and open palate design (supported by nonsplinted attachments) was fabricated for the patient following current best-practice procedures. Locator abutments were attached to the implants intraorally and torqued as per the manufacturer’s recommendations [Figure 8]. The prosthesis was tried, its fit and the occlusion were evaluated and adjusted, and it was then finished, polished, and delivered to the patient. The patient was given detailed home care instructions to maintain the prostheses and oral hygiene and placed on a biannual recall schedule.[2] [Figure 9].

DISCUSSION
In this patient, the CBCT scan confirmed the proclination of the premaxillary bone which would result in divergence between anterior and posterior implants. However, the divergence between anterior and posterior implants affects the retention and the longevity of all nonsplinted attachments (including locators).[9] Hence, to avoid the use of nonsplinted attachments on diverging implants and resulting frequent maintenance and recall visits, angulated implants were used to first correct the implant divergence and then locator

attachments were used for retaining and supporting the prosthesis.

Eger et al.[10] have stated that good function and esthetics can be achieved by restoring tilted implants with angled abutments. However, angled abutments increase the cost of the prosthesis and are technique sensitive and space intensive.[10] Use of angled abutments when there is insufficient restorative space may lead to physiologically inappropriate contours, structurally weak prostheses, poor esthetics, encroachment into freeway space, and/or suboptimal retention and stability of the prosthesis.[10]

To overcome these issues, the novel designed angulated implants were planned in the anterior maxillary region for this patient. These implants aided in achieving multi-implant parallelism and optimizing the anteroposterior spread, without the need to use angled abutments. Studies conducted by Brown and Payne[6] and Vandeweghe et al.[7] report the successful use of these novel implants for immediate replacement and immediate restoration of single teeth in the esthetic zone, but they are short-term studies with only 1 year of follow-up time. These implants are currently being used for both single and multiunit fixed and removable implant restorations. More randomized controlled studies and long-term clinical trials are necessary to evaluate the durability of these implants and their restoration.
